AMENDMENTS TO THE CLAIMS

Listing of the claims:

Claims 1-2 (canceled)

3.   (currently amended) The method of claim [[2]]48, wherein the interference noise includes crosstalk noise from high-bitrate services in the one or more binders.

Claim 4 (canceled)

5.   (currently amended) The method of claim [[1]]48, wherein the two or more receivers and the two or more transmitters utilize a Discrete Multi-Tone architecture having one or more frequency bins.

6.   (currently amended) The method of claim 5, wherein the receiving physical-layer signals across two or more receivers is performed in a frequency domain, independently for each frequency bin of the one or more frequency bins.

7.   (previously presented)   The method of claim 5, wherein the physical-layer signals coordinated across two or more transmitters include signals coordinated in a frequency domain, independently for each frequency bin of the one or more frequency bins.

8.   (currently amended) A method comprising:

creating a communications line with two or more twisted copper pairs of wire in one or more binders;

receiving from said two or more twisted pairs across two or more receivers physical layer signals that have been coordinated across two or more transmitters; and

exploiting a correlation between measured interference noise values across two or more of said receivers to reduce interference noise in the physical layer signals,

wherein the two or more receivers and the two or more transmitters utilize a Discrete Multi-Tone architecture having one or more frequency bins, and

wherein the receiving physical-layer signals across two or more receivers is performed in a frequency domain, independently for each frequency bin of the one or more frequency bins, and

The method of claim 6, further wherein the receiving physical-layer signals across two or more receivers comprises:

multiplying a transmitted symbol vector, whose elements are one or more individual symbols intended for each of the one or more transmitters, with a MIMO (Multiple Input Multiple Output) pre-processing matrix, to generate multiplied transmitted vectors;

sending the multiplied transmitted vectors to an IFFT (Inverse Fast Fourier Transform) for conversion into time-domain waveforms;

converting a received symbol vector into frequency-domain symbols via a FFT (Fast Fourier Transform); and

multiplying the frequency domain symbols with a MIMO post-processing matrix.

9.   (original) The method of claim 8, further comprising maximizing a SNR (Signal-to-Noise Ratio) in each frequency bin of the one or more frequency bins across the communications line, wherein the MIMO pre-processing matrix and the MIMO post-processing matrix are designed separately for each frequency bin of the one or more frequency bins.

10.   (original) The method of claim 9, further comprising designing the MIMO post-processing matrix used in each frequency bin of the one or more frequency bins to perform

pre-whitening the interference noise across the communications line, and

acting as a matrix FEQ (Frequency EQualizer) to equalize effects of a shortened multiline communications channel on the transmitted symbol vector.

11.   (currently amended) The method of claim 10, wherein the pre-whitening further comprises:

restricting the interference noise onto a subspace of a smallest possible dimension in a signal space; and

providing one or more independent directions in the signal space to be free of the interference noise.

12.   (original) The method of claim 11, further comprising designing the MIMO pre-processing matrix used in each frequency bin of the one or more frequency bins to

be Hermitian, so that a transmitted signal power across the two or more twisted copper pairs is preserved; and

yield an identity matrix when pre-multiplied by a main channel transfer matrix for a same frequency bin of the one or more frequency bins and the MIMO post-processing matrix for the same frequency bin of the one or more frequency bins.

Claims 13-14 (canceled)

15.   (currently amended) The system of claim [[14]]52, wherein the interference noise includes crosstalk noise from high-bitrate services in the one or more binders.

Claim 16 (canceled)

17.   (currently amended) The system of claim [[12]]52, wherein the two or more receivers and the two or more transmitters utilize a Discrete Multi-Tone architecture having one or more frequency bins.

18.   (currently amended)   The system of claim 17, wherein <u>the </u>means for receiving <u>the</u> physical-layer signals across two or more receivers is performed in a frequency domain, independently for each frequency bin of the one or more frequency bins.

19.   (previously presented)   The system of claim 17, wherein the physical-layer signals coordinated across two or more transmitters includes signals coordinated in a frequency domain, independently for each frequency bin of the one or more frequency bins.

20.   (currently amended)   <u>A system comprising:</u>
        <u>means for creating a communications line with two or more twisted copper pairs of</u> <u>wire in one or more binders;</u>
        <u>means for receiving from said two or more twisted pairs across two or more receivers</u> <u>physical layer signals that have been coordinated across two or more transmitters; and</u>
        <u>means for exploiting a correlation between measured interference noise values across</u> <u>two or more of said receivers to reduce interference noise in the physical layer signals,</u>
        <u>wherein the two or more receivers and the two or more transmitters utilize a Discrete</u> <u>Multi-Tone architecture having one or more frequency bins, and</u>
        <u>wherein the means for receiving the physical-layer signals across two or more</u> <u>receivers is performed in a frequency domain, independently for each frequency bin of the</u> <u>one or more frequency bins, and</u>
        ~~The system of claim 18,~~ <u>further </u>wherein means for receiving physical-layer signals across two or more receivers comprises:
        means for multiplying a transmitted symbol vector, whose elements are one or more individual symbols intended for each of the one or more transmitters, with a MIMO (Multiple Input Multiple Output) pre-processing matrix, to generate multiplied transmitted vectors;
        means for sending the multiplied transmitted vectors to an IFFT (Inverse Fast Fourier Transform) for conversion into time-domain waveforms;
        means for converting a received symbol vector into frequency-domain symbols via a FFT (Fast Fourier Transform); and
        means for multiplying the frequency domain symbols with a MIMO post-processing mix.

21.   (original) The system of claim 20, further comprising means for maximizing a SNR (Signal-to-Noise Ratio) in each frequency bin of the one or more frequency bins across the communications line, wherein the MIMO pre-processing matrix and the MIMO post-processing matrix are designed separately for each frequency bin of the one or more frequency bins.

22.   (original) The system of claim 21, further comprising means for designing the MIMO post-processing matrix used in each frequency bin of the one or more frequency bins to perform
        pre-whitening the interference noise across the communications line, and
        acting as a matrix FEQ (Frequency EQualizer) to equalize effects of a shortened multiline communications channel on the transmitted symbol vector.

23.   (currently amended) The system of claim 22, wherein means for pre-whitening further comprises:
        means for restricting the interference noise onto a subspace of a smallest possible dimension in a signal space; and
        means for providing one or more independent directions in the signal space to be free of the interference ~~nosie~~ noise.

24.   (original) The system of claim 23, further comprising means for designing the MIMO pre-processing matrix used in each frequency bin of the one or more frequency bins to
        be Hermitian, so that a transmitted signal power across the two or more twisted copper pairs is preserved; and
        yield an identity matrix when pre-multiplied by a main channel transfer matrix for a same frequency bin of the one or more frequency bins and the MIMO post-processing matrix for the same frequency bin of the one or more frequency bins.

Claims 25-26 (canceled)

27.   (currently amended) The computer readable medium of claim [[26]]53, wherein the interference noise includes crosstalk noise from high-bitrate services in the one or more binders.

Claim 28 (canceled)

29.   (currently amended) The computer readable medium of claim [[25]]53, wherein the two or more receivers and the two or more transmitters utilize a Discrete Multi-Tone architecture having one or more frequency bins.

30.   (currently amended) The computer readable medium of claim 29, wherein receiving physical-layer signals across the two or more receivers is performed in a frequency domain, independently for each frequency bin of the one or more frequency bins.

31.   (currently amended) The computer readable medium of claim 29, wherein the physical-layer signals coordinated across the two or more transmitters includes signals coordinated in a frequency domain, independently for each frequency bin of the one or more frequency bins.

32.   (currently amended)   ~~The computer readable medium of claim 30, further having~~
~~stored thereon computer-readable instructions, which when executed in the computer system~~
~~to receive physical-layer signals across two or more receivers, cause the computer system to:~~
A computer readable medium, having stored thereon computer-readable instructions, which
when executed in a computer system, cause the computer system to

create a communications line with two or more twisted copper pairs of wire in one or
more binders;

receive from said two or more twisted pairs across two or more receivers physical
layer signals that have been coordinated across two or more transmitters;

exploit a correlation between measured interference noise values across two or more
of said receivers to reduce interference noise in the physical layer signals;

multiply a transmitted symbol vector, whose elements are one or more individual
symbols intended for each of the one or more transmitters, with a MIMO (Multiple Input
Multiple Output) pre-processing matrix, to generate multiplied transmitted vectors;

send the multiplied transmitted vectors to an IFFT (Inverse Fast Fourier Transform)
for conversion into time-domain waveforms;

convert a received symbol vector into frequency-domain symbols via a FFT (Fast
Fourier Transform); and

multiply the frequency domain symbols with a MIMO post-processing matrix,[[.]]

wherein the two or more receivers and the two or more transmitters utilize a Discrete
Multi-Tone architecture having one or more frequency bins, and

wherein receiving physical-layer signals across the two or more receivers is
performed in a frequency domain, independently for each frequency bin of the one or more
frequency bins.

33.   (original)   The computer readable medium of claim 32, further having stored thereon
computer-readable instructions, which when executed in the computer system, cause the
computer system to maximize a SNR (Signal-to Noise Ratio) in each frequency bin of the
one or more frequency bins across the communications line, wherein the MIMO pre-
processing matrix and the MIMO post-processing matrix are designed separately for each
frequency bin of the one or more frequency bins.

34.   (original) The computer readable medium of claim 33, further having stored thereon computer-readable instruction, which when executed in the computer system, cause the computer system to design the MIMO post-processing matrix used in each frequency bin of the one or more frequency bins to:

        pre-whiten the interference noise across the communications line, and

        act as a matrix FEQ (Frequiency EQualizer) to equalize effects of a shortened multiline communications channel on the transmitted symbol vector.

35.   (currently amended) The computer readable medium of claim 34, further having stored thereon computer-readable instructions, which when executed in the computer system to pre-whiten the interference noise, cause the computer system to:

        restrict the interference noise onto a subspace of a smallest possible dimension in a signal space; and

        provide one or more independent directions in the signal space to be free of the interference noise.

36.   (original) The computer readable medium of claim 35, further having stored thereon computer-readable instructions, which when executed in the computer system, cause the computer system to:

        design the MIMO pre-processing matrix used in each frequency bin of the one or more frequency bins to

        be Hermitian, so that a transmitted signal power across the two or more twisted copper pairs is preserved; and

        yield an identity matrix when pre-multiplied by a main channel transfer matrix for a same frequency bin of the one or more frequency bins in the MIMO post-processing matrix for the same frequency bin of the one or more frequency bins.

Claims 37-38 (canceled)

39.   (currently amended) The system of claim [[38]]57, wherein the interference noise includes crosstalk noise from high-bitrate services in the one or more binders.

Claim 40 (canceled)

41.   (currently amended) The system of claim [[37]]57, wherein the two or more receivers and two or more transmitters utilize a Discrete Multi-Tone architecture having one or more frequency bins.

42.   (previously presented) The system of claim 41, wherein the physical-layer signals are received in a frequency domain, independently for each frequency bin of the one or more frequency bins.

43.   (currently amended) The system of claim 42, wherein the two or more receivers:
        multiply a transmitted symbol vector, whose elements are one or more individual symbols intended for each of the one or more transmitters, with a ~~MIO~~ MIMO (Multiple Input Multiple Output) pre-processing matrix, to generate multiplied transmitted vectors;
        send the multiplied transmitted vectors to an IFFT (Inverse Fast Fourier Transform) for conversion into time-domain waveforms;
        convert a received symbol vector into frequency-domain symbols via a FFT (Fast Fourier Transform); and
        multiply the frequency domain symbols with a MIMO post-processing matrix.

44.   (currently amended) The system of claim 43, wherein the two or more receivers maximize a SNR (Signal-to-Noise Ratio) in each frequency bin of the one or more frequency bins across the communications line, wherein the ~~MMO~~ MIMO pre-processing matrix and the ~~MJMO~~ MIMO post-processing matrix are designed separately for each frequency bin of the one or more frequency bins.

45.   (currently amended) A system comprising:

a communications line with two or more twisted copper pairs of wire in one or more binders;

two or more receivers coupled to the communications line;

two or more transmitters coupled to the communications line;

physical-layer signals coordinated across the two or more twisted copper pairs of wire by the two or more transmitters and received from said two or more copper pairs across the two or more receivers; and

the two or more receivers reducing interference noise by exploiting a correlation between measured interference noise values across the two or more receivers,

wherein the two or more receivers and two or more transmitters utilize a Discrete Multi-Tone architecture having one or more frequency bins, and

wherein the physical-layer signals are received in a frequency domain, independently for each frequency bin of the one or more frequency bins, and

further wherein the two or more receivers:

multiply a transmitted symbol vector, whose elements are one or more individual symbols intended for each of the one or more transmitters, with a MIO MIMO (Multiple Input Multiple Output) pre-processing matrix, to generate multiplied transmitted vectors;

send the multiplied transmitted vectors to an IFFT (Inverse Fast Fourier Transform) for conversion into time-domain waveforms;

convert a received symbol vector into frequency-domain symbols via a FFT (Fast Fourier Transform); and

multiply the frequency domain symbols with a MIMO post-processing matrix, and

wherein the two or more receivers maximize a SNR (Signal-to-Noise Ratio) in each frequency bin of the one or more frequency bins across the communications line, wherein the MIMO pre-processing matrix and the MIMO post-processing matrix are designed separately for each frequency bin of the one or more frequency bins, and

The system of claim 44, wherein the MIMO post-processing matrix used in each frequency bin of the one or more frequency bins pre-whiten the interference noise across the

communications line, and act as a matrix FEQ (Frequency EQualizer) to equalize effects of a shortened multiline communications channel on the transmitted symbol vector.

46.   (original) The system of claim 45, wherein the two or more receivers restrict the interference noise onto a subspace of a smallest possible dimension in a signal space; and

provide one or more independent directions in the signal space to be free of interference noise.

47.   (original) The system of claim 46, wherein the MIMO pre-processing matrix used in each frequency bin of the one or more frequency bins are Hermitian, so that a transmitted signal power across the two or more twisted copper pairs is preserved; and

yield an identity matrix when pre-multiplied by a main channel transfer matrix for a same frequency bin of the one or more frequency bins and the MIMO post-processing matrix for the same frequency bin of the one or more frequency bins.

48.   (new) A method comprising:

creating a communications line with two or more twisted copper pairs of wire in one or more binders;

coordinating physical-layer signals across two or more receivers;

coordinating the physical-layer signals across two or more transmitters; and

exploiting a correlation between measured interference noise values across two or more of said receivers to reduce interference noise in the physical layer signals,

wherein the reduced interference noise includes out of domain components of interference noise.

49.   (new) The method of claim 48 wherein coordinating the physical layer signals across two or more transmitters comprises:

multiplying a transmitted symbol vector at the transmitters by a pre-processing matrix to generate multiplied transmitted vectors.

50.   (new) The method of claim 49 wherein coordinating the physical layer signals across two or more receivers comprises:

multiplying received symbols at the receivers by a post-processing matrix.

51.   (new) The method of claim 48 wherein coordinating the physical layer signals across two or more receivers comprises:

multiplying received symbols at the receivers by a post-processing matrix.

52.   (new) A system comprising:

means for creating a communications line with two or more twisted copper pairs of wire in one or more binders;

means for coordinating physical-layer signals across two or more receivers;

means for coordinating the physical-layer signals across two or more transmitters; and

means for exploiting a correlation between measured interference noise values across two or more of said receivers to reduce interference noise in the physical layer signals,

wherein the reduced interference noise includes out of domain components of interference noise.

53.   (new) A computer readable medium, having stored thereon computer-readable instructions, which when executed in a computer system, cause the computer system to:

create a communications line with two or more twisted copper pairs of wire in one or more binders;

coordinate physical-layer signals across two or more receivers;

coordinate the physical-layer signals across two or more transmitters; and

exploit a correlation between measured interference noise values across two or more of said receivers to reduce interference noise in the physical layer signals,

wherein the reduced interference noise includes out of domain components of interference noise.

54.   (new) The computer readable medium of claim 53, further having stored thereon computer-readable instructions which coordinate the physical-layers signals across two or more transmitters and which when executed in the computer system, cause the computer system to multiply a transmitted symbol vector at the transmitters by a pre-processing matrix to generate multiplied transmitted vectors.

55.   (new) The computer readable medium of claim 54, further having stored thereon computer-readable instructions which coordinate the physical-layers signals across two or more receivers and which when executed in the computer system, cause the computer system to multiply received symbols at the receivers by a post-processing matrix.

56.   (new) The computer readable medium of claim 53, further having stored thereon computer-readable instructions which coordinate the physical-layers signals across two or more receivers and which when executed in the computer system, cause the computer system to multiply received symbols at the receivers by a post-processing matrix.

57.   (new)   A system comprising:
        a communications line with two or more twisted copper pairs of wire in one or more binders;
        two or more receivers coupled to the communications line;
        two or more transmitters coupled to the communications line;
        physical-layer signals coordinated across the two or more twisted copper pairs of wire by the two or more transmitters and received from said two or more copper pairs across the two or more receivers; and
        the two or more receivers reducing interference noise by exploiting a correlation between measured interference noise values across the two or more receivers,
        wherein the reduced interference noise includes out of domain components of interference noise.
